

Nizar's Cisco Toolbox

Configuring a Firewall in Cisco IOS:

- **enable > (passwd blank) > configure terminal**
- **interface GigabitEthernet1/?**
- **nameif inside / outside**
- **security-level 100 (no security) / 0 (full security)**
- **ip address 10.1.1.2 255.255.255.0**
- **no shutdown**
- **exit**

inside and outside networks are both assigned default security level values.

Enabling the Firewall to work on all VLANs:

- **interface -**
- **switchport mode trunk**

it now identifies each packet with a hidden tag, to keep each traffic separated from each.

Checking for Dual ISPs (Active/Active configuration):

- **enable**
- **show ip route**

if you see under the S* 0.0.0.0/0 [1/0] via x.x.x.x \n [1/0] via y.y.y.y, then it's an Active/Active configuration, if not (only one), then it's a Active/Passive configuration (Failover).

- **show interfaces summary**

Additionally, you can run this command and check for the packets sent and received, if they are received and sent from both ISPs, then it's Active/Active, if not (one showing 0 and the other running), then it's Active/Passive.

Manipulating VLANs:

- **show vlan brief**
- **configure terminal**
- **vlan 10**
- **name Production_Machines**
